Poma Session Accomplishments

Session 1 foundation | 20 October 2026

I continued the existing Flutter and SQLite starter, corrected foundation defects, implemented the selected backup exclusions, and produced a signed Android test build. The Android builds and host checks passed. The changed iOS code and physical-device checks still require verification.

Engineering work completed

- Separated the persistence contract from its SQLite implementation. The application now owns LocalRepository, while the domain remains independent of Flutter and database packages.
- Fixed paused-timer restoration so missing or empty session identity and missing start time are rejected before resume. Valid recovery preserves the original session and task, counts completion once, and leaves the next phase ready.
- Fixed the startup retry callback, which previously returned a future from Flutter setState. Retry now works and retains saved tasks; storage preparation errors show a specific privacy message.
- Added Android backup exclusions for all nine supported storage domains in legacy backup, cloud-backup, and device-transfer rules.
- Added an iOS Swift bridge that excludes the actual database directory before SQLite opens. It covers journal files, rejects outside paths, and preserves existing data if preparation fails. Native compilation and execution remain pending.

Scope and reference decisions

Kept Flutter 3.44.2 and Dart 3.12.2, the dependency lockfile, SQLite schema version 1, and the database location unchanged. Focus and break phases still start manually. Settings, tasks, and history remain local, without accounts, a backend, cloud sync, or an installed-app dependency on a computer, development server, REA, MCP, or an AI model.

Rechecked Pomatez as a desktop feature reference at its pinned commit. Retained its MIT attribution in the source, packaged asset, and app license view. The mobile app does not bundle Electron or claim full desktop parity.

Pomatez reference commit

`c2727800c6272573590911e9ee81637b89e55d5f`

Documentation and build automation

Updated the scope, architecture, reference audit, privacy guidance, release checklist, progress report, validation notes, and session prompts. CI now enforces the lockfile and includes three native iOS backup-policy tests. Those native tests have not yet run.

Verification and Delivery

Observed results from the session

Check	Result
Automated tests	31 passed, including 9 added regressions
Formatting	20 Dart files checked with no changes
Static analysis	Passed with no issues
Dependency lockfile	Offline enforcement passed unchanged
Android builds	Debug and optimized arm64 builds passed
Test APK signing	Development certificate; v2 and v3 verified
Package inspection	No internet permission; MIT notice and backup rules present
APK alignment	16 KiB ZIP and native-library alignment check passed

Files produced

The optimized Android test APK is poma-0.1.0-arm64-test.apk. It is 17,331,770 bytes (16.529 MiB), development-signed, and intended for local testing rather than store distribution.

The refreshed source archive contains 101 files. The build manifest records artifact sizes, hashes, package contents, and verification limits. These files are under D:/pomodoro/artifacts.

Installable APK SHA 256

```

Work still required

- Compile the changed iOS integration and run its three native tests on macOS. Earlier successful CI covered the original starter, not these edits.
- Test the installed app on a phone in airplane mode with the computer disconnected. No Android phone or emulator was connected during this session.
- Verify actual backup and transfer behavior on Android and iOS, plus device accessibility, startup speed, memory, battery use, and background behavior.
- Implement the required native local alerts in session 3. Production signing, branding, and some Android SDK license acceptance remain outstanding.

This is a runnable foundation, not a production-ready release. The changes remain local, uncommitted, and unpushed. Detailed evidence is recorded in docs/PROGRESS.md, docs/VALIDATION.md, and artifacts/build-manifest.json.
